Cat Problem: more than a paradox

QM = Sch-equation (dynamics) + vN-measurements (predictions)

Measurements violate conservation laws, device compensates.

Macroscopic extension of QM = Schrödinger Cat (SC)

Measurements violate conservation laws, device cannot compensate.

Macroscopic non-conservation of c.o.m. x, p, \dots , of local density, ...

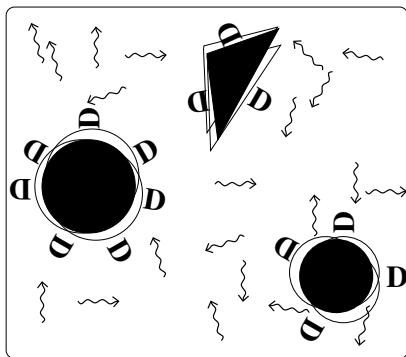

Let's disclose SCs before they arise!

G-related spontaneous disentanglement

Universal weak ($\sim G$) monitoring of mass distribution $f(r, t)$.

“Devices” act everywhere like real devices, but remain unseen.

Massive d.o.f. are disentangled (localized, collapsed, also decohered).

Shall we construct the modified Schrödinger equation?

Key equation: rate of disentanglement

SC: radius R , density ρ , mass $M = (4/3)\pi R^3 \rho$, c.o.m. x
 Just notation, with no dynamic role:

$$U(|x - x'|) = -G\rho^2 \int_{|r-x|\leq R} d^3r \int_{|r'-x'|\leq R} d^3r' \frac{1}{|r - r'|}$$

The proposed disentanglement rate:

$$\frac{1}{\tau_G} = \frac{2}{\hbar} [U(x - x') - U(0)]$$

For $\Delta x = |x - x'| \ll R$ (i.e., for small coherent spread):

$$\frac{1}{\tau_G} = \text{const} \times \frac{M\omega_G^2}{\hbar} (\Delta x)^2$$

where $\omega_G = \sqrt{4\pi G\rho/3}$ is the “Newton oscillator” frequency.

Equilibrium rate of disentanglement

Modified QM:

$$d\psi(x, q)/dt = \text{Sch. lin. term} + G \times \text{stoch. nonlin. term.}$$

q : SC internal d.o.f. plus light environmental d.o.f.

Sch. increases Δx — G -term decreases Δx .

Equilibrium condition:

$$\frac{\hbar}{M(\Delta x)^2} \sim \frac{M\omega_G^2(\Delta x)^2}{\hbar}$$

Equilibrium rate:

$$\frac{1}{\tau_G^{\text{eq}}} \sim \omega_G \sim \frac{1}{\text{hour}}$$

That's too slow, would be irrelevant in Nature. Loophole?

Mass density spatial resolution

Issue: low equilibrium disentanglement rate $\omega_G = \sqrt{4\pi G\rho/3}$.
 Loophole: resolve microscopic structure, $\rho \Rightarrow \rho^{\text{nucl}}$.

$$\frac{1}{\tau_G} = \omega_G \sim \frac{1}{\text{hour}}$$

$$\frac{1}{\tau_G} = \omega_G^{\text{nucl}} \sim \frac{1}{\text{ms}}$$

Bad news: Nuclear mass distribution is vaguely defined!

Good news: High(er) disent. rate (1/ms) can be relevant for Nature.

Bad news: Local environmental decoherence is always faster.

Experimental prediction?

If G-related disentanglement is cause of gravity?

Why should it be?

Consider free massive object, ignore environment (don't need to):

- C.o.m. $p \neq \text{const}$ under G-related spontaneous disentanglement.
- We prefer to restore p -conservation, at least on average.
- In equilibrium, c.o.m. world-line is wiggling.
- Wiggle is universal.
- Wiggly world-line *is the* geodetic one.
- This assumes gravitational forces along the world-line.
- These forces might restore p -conservation.
- These forces emerge from disentanglement at rate $1/\tau_G \sim 1/\text{ms}$.
- Mean of these forces constitute the object's Newton field.
- Newton field has the emergence time scale $\tau_G \sim 1\text{ms}$.

Testing gravity's laziness

A fully classical proposal to test the “delay” τ_γ of the Newton field of a mass M moving along the path x_t :

$$\Phi(r, t) = \int_0^\infty \frac{-GM}{|r - x_{t-\tau}|} e^{-\tau/\tau_\gamma} d\tau/\tau_\gamma$$

valid (i) in the free falling reference frame where $M\ddot{x}_t$ is equal to the non-gravitational forces; (ii) in the t-dependent co-moving system where $\dot{x}_t = 0$.

(ii) guarantees boost-invariance. (i-ii) say Newton law is restored in absence of non-gravitational forces.

Example: Revolving at angular frequency Ω under non-gravitational force, the accelerated source yields in the center $(1 + \Omega^2\tau_\gamma^2/2) \times$ the standard Newtonian force.

There must be feasible tests of $\tau_\gamma = \tau_G = 1ms!$
